DESCRIPTION

NOVEL DNA AND PROCESS FOR PREPARING PROTEIN USING THE DNA

FIELD OF TECHNOLOGY

The present invention relates to a novel DNA and a process for preparing a protein which possesses an activity to inhibit osteoclast differentiation and/or maturation (hereinafter called osteoclastogenesis-inhibitory activity) by a genetic engineering technique using the DNA. More particularly, the present invention relates to a genomic DNA encoding a protein OCIF which possesses an osteoclastogenesis-inhibitory activity and a process for preparing said protein by a genetic engineering technique using the genomic DNA.

BACKGROUND OF THE INVENTION

Human bones are constantly repeating a process of resorption and formation. Osteoblasts controlling formation of bones and osteoclasts controlling resorption of bones take major roles in this process. Osteoporosis is a typical disease caused by abnormal metabolism of bones. This disease is caused when bone resorption by osteoclasts exceeds bone formation by osteoblasts. Although the mechanism of this disease is still to be elucidated completely, the disease causes the bones to ache, makes the bones fragile, and may result in fracturing of the bones. As the population of the aged increases, this disease results in an increase in the number of bedridden aged people which becomes a social problem. Urgent development of a therapeutic agent for this disease is strongly desired. Disease due to a

33040

decrease in bone mass is expected to be treated by controlling bone resorption, accelerating bone formation, or improving balance between bone resorption and formation.

Osteogenesis is expected to be increased by accelerating proliferation, differentiation, or activation of the cells controlling the bone formation, or by controlling proliferation, differentiation, or activation of the cells involved in bone

resorption. In recent years, strong interest has been directed to physiologically active proteins (cytokines) exhibiting such activities as described above, and energetic research is ongoing on this subject. The cytokines which have been reported to accelerate proliferation or differentiation of osteoblasts include the proteins of fibroblast growth factor family (FGF: Rodan S. B. et al., Endocrinology vol. 121, p 1917, 1987), insulin-like growth factor I (IGF-I: Hock J. M. et al., Endocrinology vol. 122, p 254, 1988), insulin growth factor II (IGF-II: McCarthy T. et al., Endocrinology vol. 124, p 301, 1989), Activin A (Centrella M. et al., Mol. Cell. Biol., vol. 11, p 250, 1991), transforming growth factor- β , (Noda M., The Bone, vol. 2, p 29, 1988), Vasculotropin (Varonique M. et al., Biochem. Biophys. Res. Commun., vol. 199, p 380, 1994), and the protein of heterotopic bone formation factor family (bone morphogenic protein: BMP: BMP-2; Yanaguchi A. et al., J. Cell Biol. vol. 113, p 682, 1991, OP-1; Sampath T. K. et al., J. Biol. Chem. vol. 267, p 20532, 1992, and Knutson R. et al., Biochem. Biophys. Res. Commun. vol. 194, p 1352, 1993).

On the other hand, as the cytokines which suppress

330400

differentiation and/or maturation of osteoclasts, transforming growth factor- β (Chenu C. et. al., Proc. Natl. Acad. Sci. USA, vol. 85, p 5683, 1988), interleukin-4 (Kasano K. et al., Bone-Miner., vol. 21, p 179, 1993), and the like have been reported. Further, as the cytokines which suppress bone resorption by osteoclast, calcitonin (Bone-Miner., vol. 17, p 347, 1992), macrophage colony stimulating factor (Hattersley G. et al., J. Cell. Physiol. vol. 137, p 199, 1988), interleukin-4 (Watanabe, K. et al., Biochem. Biophys. Res. Commun. vol. 172. P 1035, 1990), and interferon- γ (Gowen M. et al., J. Bone Miner. Res., vol. 1, p 46.9, 1986) have been reported.

These cytokines are expected to be used as agents for treating diseases accompanying bone loss by accelerating bone formation or suppressing bone resorption. Clinical tests are being undertaken to verify the effect of improving bone metabolism of some cytokines such as insulin-like growth

factor-I and the heterotopic bone formation factor family. In addition, calcitonin is already commercially available as a therapeutic agent for osteoporosis and a pain relief agent. At present, drugs for clinically treating bone diseases or shortening the period of treatment of bone diseases include activated vitamin D₃, calcitonin and its derivatives, and hormone preparations such as estradiol agent, ipriflavon or calcium preparations. These agents are not necessarily satisfactory in terms of the efficacy and therapeutic results. Development of a novel therapeutic agent which can be used in

330400

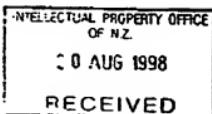

M. et al., Biochem. Biophys. Res. commun. vol.199, p380, 1994), and bone morphogenic protein (BMP:BMP-2; Yamaguchi, A et al., J. Cell Biol. vol. 113, p682, 1991, OP-1; Sampath T.K. et al., J. Biol. Chem. vol. 267, p20532, 1992, Knutson R. et al., Biochem. Biophys. Res. Commun. vol. 194, p1352, 1992) were reported.

[0004]

On the other hand, as a cytokine inhibiting osteoclast formation, that is, differentiation and/or maturation of osteoclast, transforming growth factor- β (Chen C. et al., Proc. Natl. Acad. Sci. USA, vol.85, p5683, 1988) and interleukin-4 (Kasano K. et al., Bone-Miner., vol.21, p179, 1993) were reported. And as a cytokine inhibiting bone resorption induced by osteoclast, calcitonin (Bone Miner., vol.17, p347, 1992), macrophage colony-stimulating factor (Hattersley G. et al., J. Cell. Physiol. vol.137, p199, 1988), interleukin-4 (Watanabe,K. et al., Biochem. Biophys. Res. Commun., vol.172, p1035, 1990) and interferon- τ (Gowen M. et al., J. Bone Miner. Res., vol.1, p469, 1986) were reported.

[0005]

These cytokines are expected to improve osteopenia by stimulating bone formation and inhibiting of bone resorption and clinical trial of some of the above-mentioned cytokines such as insulin like growth factor-I and cytokine of bone morphogenic protein family are being carried out as agents improving bone metabolism. Calcitonin has been already saled as a therapeutic agent for osteoporosis or a pain relieving agent. In addition, for the treatment of metabolic bone diseases and for shortening treatment duration, active vitamin D₃, calcitonin and analogue

330400

thereof, hormones such as estradiol, ipriflavone or calcium agent etc. is clinically used at present. However, by these therapeutic methods, effects of the treatment is not necessarily satisfactory. Therefore, development of a novel therapeutic agent is desired in replace of the above methods.

[0006]

[Problems to be Solved by the Invention]

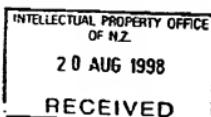

Considering these situations, the present inventors have eagerly studied and found that OCIF protein having an inhibitory activity on osteoclast formation was already recovered from culture medium of human embryonic lung fibroblast cell line IMR-90(ATCC deposit number is CCL186) (PCT/JP96/00374). Further, the present inventors have studied on the origin of OCIF having an inhibitory activity on osteoclast formation and determined base sequence of genomic DNA of human originated OCIF. An object of the present invention is to provide a genomic DNA encoding OCIF protein having an inhibitory activity on osteoclast formation and a method of preparing said protein by genetic engineering manipulation.

[0007]

[Means to Solve the Problem]

The present invention relates to a genomic DNA encoding protein OCIF having an inhibitory activity on osteoclast formation and a method of preparing said protein thereby by genetic engineering manipulation.

The DNA of the present invention comprises base sequence of

immunological diagnosis of such diseases.

33046

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 shows a result of Western Blotting analysis of the protein obtained by causing genomic DNA of the present invention to express a protein in Example 4 (iii), wherein lane 1 indicates a size marker, lane 2 indicates the culture broth of COS7 cells in which a vector pWESR α OCIF (Example 4 (iii)) has been transfected, and lane 3 is the culture broth of COS7 cell in which a vector pWESR α (control) has been transfected.

BEST MODE FOR CARRYING OUT THE INVENTION

The genomic DNA encoding the protein OCIF which exhibits osteoclastogenesis-inhibitory activity in the present invention can be obtained by preparing a cosmid library using a human placenta genomic DNA and a cosmid vector and by screening this library using DNA fragments which are prepared based on the OCIF cDNA as a probe. The thus-obtained genomic DNA is inserted into a suitable expression vector to prepare an OCIF expression cosmid. A recombinant type OCIF can be obtained by transfecting the genomic DNA into a host organism such as various types of cells or microorganism strains and causing the DNA to express a protein by a conventional method. The resultant protein exhibiting osteoclastogenesis-inhibitory activity (an osteoclastogenesis-inhibitory factor) is useful as an agent for the treatment and improvement of diseases involving a decrease in bone mass such as osteoporosis and other diseases relating to bone metabolism abnormality and also as an antigen to prepare antibodies for establishing immunological diagnosis of such

330400

diseases. The protein of the present invention can be prepared as a drug composition for oral or non-oral administration. Specifically, the drug composition of the present invention containing the protein which is an osteoclastogenesis-inhibitory factor as an active ingredient can be safely administered to humans and animals. As the form of drug composition, a composition for injection, composition for intravenous drip, suppository, nasal agent, sublingual agent, percutaneous absorption agent, and the like are given. In the case of the composition for injection, such a composition is a mixture of a pharmacologically effective amount of the osteoclastogenesis-inhibitory factor of the present invention and a pharmaceutically acceptable carrier. The composition may further comprise amino acids, saccharides, cellulose derivatives, and other excipients and/or activation agents, including other organic compounds and inorganic compounds which are commonly added to a composition for injection. When an injection preparation is prepared using the osteoclastogenesis-inhibitory factor of the present invention and these excipients and activation agents, a pH adjuster, buffering agent, stabilizer, solubilizing agent, and the like may be added if necessary to prepare various types of injection agents.

The present invention will now be described in more detail by way of examples which are given for the purpose of illustration and not intended to be limiting of the present invention.

Example 1

330400

<Preparation of a cosmid library>

A cosmid library was prepared using human placenta genomic DNA (Clonetech; Cat. No. 6550-2) and pWE15 cosmid vector (Stratagene). The experiment was carried out following principally the protocol attached to the pWE15 cosmid vector kit of Stratagene Company, provided Molecular Cloning: A Laboratory Manual (Cold Spring Harbor Laboratory (1989)) was referred to for common procedures for handling DNA, *E. coli*, and phage.

(i) Preparation of restriction enzyme digest of human genomic DNA

Human placenta genomic DNA dissolved in 750 μ l of a solution containing 10 mM Tris-HCl, 10 mM MgCl₂, and 100 mM NaCl was added to four 1.5 ml Eppendorf tubes (tube A, B, C, and D) in the amount of 100 μ g each. Restriction enzyme MboI was added to these tubes in the amounts of 0.2 unit for tube A, 0.4 unit for tube B, 0.6 unit for tube C, and 0.8 unit for tube D, and DNA was digested for 1 hour. Then, EDTA in the amount to make a 20 mM concentration was added to each tube to terminate the reaction, followed by extraction with phenol/chloroform (1:1). A two-fold amount of ethanol was added to the aqueous layer to precipitate DNA. DNA was collected by centrifugation, washed with 70% ethanol, and DNA in each tube was dissolved in 100 μ l of TE (10mM Tris-HCl (pH 8.0) + 1mM EDTA) buffer solution, hereinafter called TE. DNA in four tubes was combined in one tube and incubated for 10 minutes at 68°C. After cooling to room

330400

temperature, the mixture was overlayed onto a 10%-40% linear sucrose gradient which was prepared in a buffer containing 20 mM Tris-HCl (pH 8.0), 5mM EDTA, and 1M NaCl in a centrifuge

tube (38 ml). The tube was centrifuged at 26,000 rpm for 24 hours at 20°C using a rotor SRP28SA manufactured by Hitachi, Ltd. and 0.4 ml fractions of the sucrose gradient was collected using a fraction collector. A portion of each fraction was subjected to 0.4% agarose electrophoresis to confirm the size of DNA. Fractions containing DNA with a length of 30 kb (kilo base pair) to 40 kb were thus combined. The DNA solution was diluted with TE to make a sucrose concentration to 10% or less and 2.5-fold volumes of ethanol was added to precipitate DNA. DNA was dissolved in TE and stored at 4°C.

(ii) Preparation of cosmid vector

The pWE15 cosmid vector obtained from Stratagene Company was completely digested with restriction enzyme BamHI according to the protocol attached to the cosmid vector kit. DNA collected by ethanol precipitation was dissolved in TE to a concentration of 1 mg/ml. Phosphoric acid at the 5'-end of this DNA was removed using calf small intestine alkaline phosphatase, and DNA was collected by phenol extraction and ethanol precipitation. The DNA was dissolved in TE to a concentration of 1 mg/ml.

(iii) Ligation of genomic DNA to vector and in vitro packaging

1.5 micrograms of genomic DNA fractionated according to size and 3 μ g of pWE15 cosmid vector which was digested with

330400

restriction enzyme BamHI were ligated in 20 μ l of a reaction solution using Ready-To-Go T4DNA ligase of Pharmacia Company. The ligated DNA was packaged in vitro using GigapackTM II packaging extract (Stratagene) according to the protocol. After the packaging reaction, a portion of the reaction mixture was diluted stepwise with an SM buffer solution and mixed with *E. coli* XL1-Blue MR (Stratagene) which was suspended in 10 mM MgCL₂ to cause phage to infect, and plated onto LB agar plates containing 50 μ g/ml of ampicillin. The number of colonies produced was counted. The number of colonies per 1 μ l of packaging reaction was calculated based on this result.

(iv) Preparation of a cosmid library

The packaging reaction solution thus prepared was mixed with *E. coli* XL1-Blue MR and the mixture was plated onto agarose plates containing ampicillin so as to produce 50,000 colonies per agarose plate having a 15 cm of diameter. After incubating the plate overnight at 37°C, an LB culture medium was added in the amount of 3 ml per plate to suspend and collect *E. coli* cells. Each agarose plate was again washed with 3 ml of LB culture medium and the washing was combined with the original suspension of *E. coli*. The *E. coli* collected from all agarose plates was placed in a centrifuge tube, glycerol was added to a concentration of 20%, and ampicillin was further added to make a final concentration of 50 μ g/ml. A portion of the *E. coli* suspension was removed and the remainder was stored at -80°C. The removed *E. coli* was diluted stepwise and plated onto agar plates to estimate the number of colonies per 1 ml of

suspension.

Example 2

330400

<Screening of cosmid library and purification of colony>

A nitrocellulose filter (Millipore) with a diameter of 14.2 cm was placed on each LB agarose plate with a diameter of 15 cm which contained 50 µg/ml of ampicillin. The cosmid library was plated onto the plates so as to produce 50,000 colonies of *E. coli* per plate, followed by incubation overnight at 37°C. *E. coli* on the nitrocellulose filter was transferred to another nitrocellulose filter according to a conventional method to obtain two replica filters. According to the protocol attached to the cosmid vector kit, cosmid DNA in the *E. coli* on the replica filters was denatured with an alkali, neutralized, and immobilized on the nitrocellulose filter using a Stratalinker (Stratagene). The filters were heated for two hours at 80°C in a vacuum oven. The nitrocellulose filters thus obtained were hybridized using two kinds of DNA produced, respectively, from 5'-end and 3'-end of human OCIF cDNA as probes. Namely, a plasmid was purified from *E. coli* pKB/OIF10 (deposited at The Ministry of International Trade and Industry, the Agency of Industrial Science and Technology, Biotechnology Laboratory, Deposition No. FERM 3P-5267) containing OCIF cDNA. The plasmid containing OCIF cDNA was digested with restriction enzymes KpnI and EcoRI. Fragments thus obtained were separated using agarose gel electrophoresis. KpnI/EcoRI fragment with a length of 0.2 kb was purified using a QIAEX II gel extraction kit (Qiagen). This DNA was labelled with ³²P using the Megaprime DNA labelling

System (Amersham) (5'-DNA probe). Apart from this, a BamHI/EcoRV fragment with a length of 0.2 kb which was produced from the above plasmid by digestion with restriction enzymes BamHI and EcoRV was purified and labeled with ^{32}p (3'-DNA probe). One set of the replica filters described above was hybridized with the 5'-DNA probe and the other with the 3'-DNA probe. Hybridization and washing of the filters were carried out according to the protocol attached to the cosmid vector kit. Autoradiography detected several positive signals with each probe. One colony which gave positive signals with both probes was identified. The colony on the agar plate, which corresponding to the signal on the autoradiogram was isolated and purified. A cosmid was prepared from the purified colony by a conventional method. This cosmid was named pWEOCIF. The size of the human genomic DNA fragment contained in this cosmid was about 38 kb.

Example 3

< Determination of the nucleotide sequence of the human OCIF genomic DNA fragment >

(i) Subcloning of the OCIF genomic DNA fragment

Cosmid pWEOCIF was digested with restriction enzyme EcoRI. After the separation of the DNA fragments thus produced by electrophoresis using a 0.7% agarose gel, the DNA fragments were transferred to a nylon membrane (Hybond -N, Amasham) by the Southern blot technique and immobilized on the nylon membrane using Stratalinker (Stratagene). On the other hand, plasmid pBKOCIF was digested with restriction enzyme EcoRI and a 1.6

330400

kb fragment containing human OCIF cDNA was isolated by agarose gel electrophoresis. The fragment was labeled with ^{32}P using the Megaprime DNA labeling system (Amasham).

Hybridization of the nylon membrane described above with the ^{32}P -Labelled 1.6=kb OCIF cDNA, performed according to a conventional method, detected DNA fragments with a size of

6 kb, 4 kb, 3.6 kb, and 2.6 kb. These fragments hybridized with the human OCIF cDNA were isolated using agarose gel electrophoresis and individually subcloned into an EcoRI site of pBluescript II SK + vector (Stratagene) by a conventional method. The resulting plasmids were named respectively, pBSE 6, pBSE 4, pBSE 3.6, and pBSE 2.6.

(ii) Determination of the nucleotide sequence

The nucleotide sequences of the human OCIF genomic DNA fragments which were subcloned into the plasmid were determined using the ABI Dideoxy Terminator Cycle Sequencing Ready Reaction kit (Perkin Elmer) and the 373 Sequencing System (Applied Biosystems). The primers used for the determination of the nucleotide sequences were synthesized based on the nucleotide sequence of human OCIF

cDNA (Sequence ID No. 4 in the Sequence Table). The nucleotide sequences thus determined are given as the Sequences No. 1 and No. 2 in the Sequence Table. The Sequence ID No. 1 includes the first exon of the OCIF gene and the Sequence ID No. 2 includes the second, third, fourth, and fifth exons. A stretch of about 17 kb is present between the first and second exons.

Example 4

<Production of recombinant OCIF using COS-7 cells>

330400

(i) Preparation of OCIF genomic DNA expression cosmid

To express OCIF genomic DNA in animal cells, an expression unit of expression plasmid pcDL-SR α 296 (Molecular and Cellar Biology, vol. 8, P466-472, 1988) was inserted into cosmid vector pWE15 (Stratagene). First of all, the expression plasmid pcDL-SR α 296 was digested with a restriction enzyme Sal I to cut out expression unit with a length of about 1.7 kb which includes an SR α promotor, SV40 later splice signal, poly (A) addition signal, and so on. The digestion products were separated by agarose gel electrophoresis and the 1.7-kb fragment was purified using the QIAEX II gel extraction kit (Qiagen). On the other hand, cosmid vector pWE15 was digested with a restriction enzyme EcoRI and fragments were separated using agarose gel electrophoresis. pWE15 DNA of 8.2 kb long was purified using the QIAEX II gel extraction kit (Qiagen). The ends of these two DNA fragments were blunted using a DNA blunting kit (Takara Shuzo), ligated using a DNA ligation kit (Takara Shuzo), and transfected into E. coli DH5 α (Gibco BRL). The resultant transformant was grown and the expression cosmid pWESR α containing the expression unit was purified using a Qiagen column (Qiagen).

The cosmid pWE OCIF containing the OCIF genomic DNA fragment with a length of about 38 kb obtained in (i) above was digested with a restriction enzyme NotI to cut out the OCIF genomic DNA fragment of about 38 kb. After separation by agarose gel electrophoresis, the DNA fragment was purified using the QIAEX II gel extraction kit (Qiagen). On the other hand, the expression cosmid pWESR α was

330400

digested with a restriction enzyme EcoRI and the digestion product was extracted with phenol and chloroform, ethanol-precipitated, and dissolved in TE.

pWESR α digested with a restriction enzyme EcoRI and an EcoRI-XmnI-NotI adapter (#1105, #1156 New England Biolaboratory Co.) were ligated using T4 DNA ligase (Takara Shuzo Co., Ltd.). After removal of the free adapter by agarose gel electrophoresis, the product was purified using QIAEX gel extraction kit (Qiagen). The OCIF genomic DNA fragment with a length of about 37 kb, which was derived from the digestion with restriction enzyme NotI and the pWESR α to which the adapter was attached were ligated using T4 DNA ligase (Takara Shuzo). The DNA was packaged in vitro using the Gigapack packaging extract (Stratagene) and transfected to *E. coli* XL1-BlueMR (Stratagene). The resultant transformant was grown and the expression cosmid pWESR α OCIF which contained OCIF genomic DNA fragment was purified using a Qiagen column (Qiagen). The OCIF expression cosmid pWESR α OCIF was ethanol-precipitated, dissolved in sterile distilled water and used in the following analysis.

(ii) Transient expression of OCIF genomic DNA and measurement of OCIF activity

A recombinant OCIF was expressed as described below using the OCIF expression cosmid pWESR α OCIF obtained in (i) above and its activity was measured. COS-7 (8×10^3 cells/well) cells (Riken Cell Bank, RCB0539) were plated in a 6-well plate using DMEM culture medium (Gibco BRL) containing 10% fetal bovine serum (Gibco BRL). On the following day, the culture

330400

medium was removed and cells were washed with serum-free DMEM culture medium. The OCIF expression cosmid pWESR α OCIF which had been diluted with OPTI-MEM culture medium (Gibco BRL) was mixed with Lipopfectamine and the mixture was added to the cells in each well according to the attached protocol. The expression cosmid pWESR α was added to the cells in the same manner as a control. The amount of the cosmid DNA and Lipopfectamine was respectively 3 μ g and 12 μ l. After 24 hours, the culture medium was removed and 1.5 ml of fresh EX-CELL 301 culture medium (JRH Bioscience) was added to each well. The culture medium was recovered after 48 hours and used as a sample for the measurement of OCIF activity. The measurement of OCIF activity was carried out according to the method described by Kumegawa, M. et al. (Protein, Nucleic Acid, and Enzyme, Vol. 34, p 999 (1989)) and the method of TAKAHASHI, N. et al. (Endocrinology vol. 122, p 1373 (1988)). The osteoclast formation from bone marrow cells isolated from mice aged about 17 days in the presence of activated vitamin D, was evaluated by the induction of tartaric acid resistant acidic phosphatase activity. The reduction of

the acid phosphatase was measured and used as the activity of the protein which possesses osteoclastogenesis-inhibitory activity (OCIF). Namely, 100 μ l of a OCIF sample which was diluted with α -MEM culture medium (Gibco BRL) containing 2×10^{-8} M activated vitamin D, and 10% fetal bovine serum was added to each well of a 96 well micro plate. Then, 3×10^3 bone marrow cells isolated from mice (about 17-days old) suspended in 100 μ l of α -MEM culture medium containing 10% fetal bovine serum

330409

were added to each well of the 96 well micro plate and cultured for a week at 37°C and 100% humidity under 5% CO₂ atmosphere. On days 3 and 5, 160 µl of the conditioned medium was removed from each well, and 160 µl of a sample which was diluted with α-MEM culture medium containing 1x10⁻⁸ M activated vitamin D₃ and 10% fetal bovine serum was added. On day 7, the cells were washed with a phosphate buffered saline and fixed with a ethanol/acetone (1:1) solution for one

minute at room temperature. The osteoclast formation was detected by staining the cells using an acidic phosphatase activity measurement kit (Acid Phosphatase, Leucocyte, Cat. No. 387-A, Sigma Company). A decrease in the number of cells positive to acidic phosphatase activity in the presence of tartaric acid was taken as the OCIF activity. The results are shown in Table 1, which indicates that the conditioned medium exhibits the similar activity to natural type OCIF obtained from the IMR-90 culture medium and recombinant OCIF produced by CHO cells.

330400

TABLE 1

Activity of OCIF in the conditioned medium of COS-7 cells.

Dilution	1/10	1/20	1/40	1/80	1/160	1/320
OCIF genomic DNA introduced	++	++	++	++	+	-
Vector introduced	-	-	-	-	-	-
Untreated	-	-	-	-	-	-

"++" indicates an activity inhibiting 80% or more of osteoclast formation, "+" indicates an activity inhibiting 30-80% of osteoclast formation, and "-" indicates that no inhibition of osteoclast formation is observed.

(iii) Identification of the product by Western Blotting

A buffer solution (10 μ l) for SDS-PAGE (0.5 M Tris-HCl, 20% glycerol, 4% SDS, 20 μ g/ml bromophenol blue, pH 6.8) was added to 10 μ l of the sample for the measurement of OCIF activity prepared in (ii) above. After boiling for 3 minutes at 100°C, the mixture was subjected to 10% SDS polyacrylamide electrophoresis under non-reducing conditions. The proteins were transferred from the gel to a PVDF membrane (ProBlott, Perkin Elmer) using semi-dry blotting apparatus (Biorad). The membrane was blocked and incubated for 2 hours at 37°C together with a horseradish peroxidase-labeled anti-OCIF antibody obtained by labelling the previously obtained anti-OCIF antibody with horseradish peroxidase according to a conventional method. After washing, the protein which bound the anti-OCIF antibody was detected using the ECL system (Amasham). As shown in Figure 1, two bands, one with a molecular weight of about 120 kilo dalton and the other 60 kilo dalton, were detected in

330400

the supernatant obtained from the culture broth of COS-7 cells in which pWESR α OCIF was transfected. On the other hand, these two bands with a molecular weight of about 120 kilo dalton and 60 kilo dalton were not detected in the supernatant obtained from the culture broth of COS-7 cells in which pWESR α vector was transfected, confirming that the protein obtained was OCIF.

INDUSTRIAL APPLICABILITY

The present invention provides a genomic DNA encoding a protein OCIF which possesses an osteoclastogenesis-inhibitory activity and a process for preparing this protein by a genetic engineering technique using the genomic DNA. The protein obtained by expressing the gene of the present invention exhibits an osteoclastogenesis-inhibitory activity and is useful as an agent for the treatment and improvement of diseases involving a decrease in the amount of bone such as osteoporosis, other diseases resulting from bone metabolism abnormality such as rheumatism, degenerative joint disease, and multiple myeloma. The protein is further useful as an antigen to establish antibodies useful for an immunological diagnosis of such diseases.

[Brief Description of the Drawing]

[Figure 1]

It exhibits the result of Western blotting of the protein obtained by the expression of the genomic DNA of the present invention in example 3(iii)

[Explanation of Referenced Numerals]

- 1: marker
- 2: supernatant of culture medium of COS-7 cell transfected with vector pWESR α OCIF (example 3(iii))
- 3: supernatant of culture medium of COS-7 transfected with vector pWESR α (control)

[Document] Abstract

[Abstract]

[Problems to be Solved]

A novel DNA encoding a protein having an inhibitory activity on osteoclast formation and a method of preparing said protein thereby.

[Means to Solve the Problems]

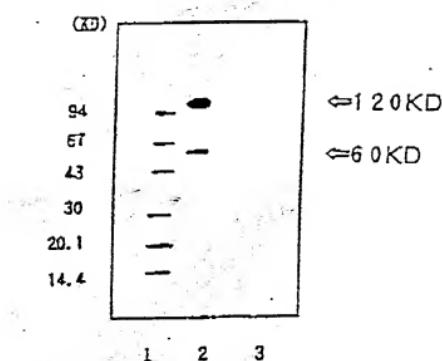

DNA described in Seq.ID.No.1 and 2.

A method of preparing a protein with a molecular weight of about 60 kD (under reducing conditions), and about 60 kD and about 120 kD (under non-reducing conditions) having an inhibitory action on osteoclast formation by inserting said DNA into expression vector and by genetic engineering manipulation. This protein has an inhibitory action on osteoclast formation and can be useful for curing osteoporosis and rheumatism.

CLAIMS:

1. A DNA comprising the nucleotide sequences of the Sequences No. 1 and No. 2 in the Sequence Table.
2. The DNA according to claim 1, wherein the Sequence ID No. 1 includes the first exon of the OCIF gene and the Sequence ID No. 2 includes the second, third, fourth, and fifth exons.
3. A protein exhibiting the activity of inhibiting differentiation and/or maturation of osteoclasts and having the following physicochemical characteristics,
 - (a) molecular weight (SDS-PAGE):
 - (i) Under reducing conditions: about 60 kD,
 - (ii) Under non-reducing conditions: about 60 kD and about 120 kD;
 - (b) amino acid sequence:
includes an amino acid sequence of the Sequence ID No. 3 in the Sequence Table,
 - (c) affinity:
exhibits affinity to a cation exchanger and heparin, and
 - (d) heat stability:
 - (i) the osteoclastogenesis-inhibitory activity is reduced when treated with heat at 70°C for 10 minutes or at 56°C for 30 minutes,
 - (ii) the osteoclastogenesis-inhibitory activity is lost when treated with heat at 90°C for 10 minutes.
4. A process for producing a protein exhibiting an

44
380400

activity of inhibiting differentiation and/or maturation of osteoclasts and having the following physicochemical characteristics,

(a) molecular weight (SDS-PAGE):

- (i) Under reducing conditions: about 60 kD,
- (ii) Under non-reducing conditions: about 60 kD and about 120 kD;

(b) amino acid sequence:

includes an amino acid sequence of the Sequence ID No. 3 of the Sequence Table,

(c) affinity:

exhibits affinity to a cation exchanger and heparin, and

(d) heat stability:

- (i) the osteoclastogenesis-inhibitory activity is reduced when treated with heat at 70°C for 10 minutes or at 56°C for 30 minutes,
- (ii) the osteoclastogenesis-inhibitory activity is lost when treated with heat at 90°C for 10 minutes,

the process comprising inserting a DNA including the nucleotide sequences of the sequences No. 1 and No. 2 in the Sequence Table into an expression vector, producing a vector capable of expressing a protein having the above-mentioned physicochemical characteristics and exhibiting the activity of inhibiting differentiation and/or maturation of osteoclasts, and producing this protein by a genetic engineering technique.
